MISSISSIPPI POPULATION PROJECTIONS

2015, 2020, and 2025

Population projections are routinely updated as new information becomes available. This report contains new population projections for Mississippi and its 82 counties; the new figures update and replace all earlier projections.

Population projections are the numerical outcomes of a set of assumptions about current and future trends in fertility, mortality, and migration. If the assumptions are borne out, the projected numbers will be exactly on target. But, in practice, this never happens because much of human behavior is unpredictable. Migration trends are particularly volatile, as migrants respond quickly to job losses, on the one hand, and economic opportunities, on the other. Thus care and judgment are required on the part of users: projections must always be used with due attention to their underlying assumptions.

Agencies responsible for doing population projections often produce three or more alternative sets of numbers, leaving users free to choose which set to use. The alternatives may be characterized, for example, as “high,” “medium,” and “low.” Due to resource constraints, this cannot be done in Mississippi. Hence, users may choose to adjust the projected numbers in this report up or down based on their individual needs, goals, and specialized knowledge of the geographic area under consideration.

SPECIAL CONSIDERATIONS

Special considerations applicable to this set of population projections include the following:

1. Base population - The base population for these projections was the 2010 decennial census count for each county. The base population was carried forward to 2015, 2020, and 2025 using a cohort component method, which incorporates separate assumptions for each of the three sources of population change: births, deaths, and migration.

2. Time span - The longer the projection period, the greater the scope for error. Although planners often prefer longer-range projections, a five-year period is probably optimal as a projection target. But given the demand for such statistics in Mississippi, these projections were carried forward to the year 2025.

3. Size of area or group - The smaller the geographic area, the greater the potential for error. Projections for states, for example, are more reliable than those for cities or counties. Figures for age, sex, or racial subgroups are less reliable than totals, due to the fact that small numbers often

behave erratically. Hence projections for small counties and small categories must be used with caution.

4. Presence of special populations - Such institutions as colleges, prisons, and military bases typically consist of particular age categories (young adults, for example), and may be sex-specific as well. Their growth or decline is unlikely to parallel general population trends in the county of interest. Hence it is necessary to handle counties containing special populations separately, and additional assumptions were required regarding their size, composition, and growth trends.

PROJECTION METHODOLOGY

The cohort component method is the projection technique used in this report. This approach requires detailed input data specific to the geographic level of interest -- in this case, the county level. The cohort component method carries each sex/race group in the target population individually forward in time, by five-year time intervals and for five-year age categories. In addition, special procedures are required to take account of births occurring after the beginning date of the projection period.

DATA AND ASSUMPTIONS

1. Fertility - A set of five-year age-specific fertility rates is required as input data for each five-year projection interval. Data on births were obtained from the Mississippi State Department of Health. Fertility rates were calculated using the average number of births by age of mother for the period 2007–2009 combined with estimates of the number of women in each category in 2008. Rates were derived separately for whites and nonwhites. A three-year average was used in order to avoid reliance on a single year's data, since any one year may be atypical. Because there was no reliable basis for assuming that fertility rates would rise or fall in future years, the base rates were held constant for the duration of the projection period.

2. Mortality - Five-year survival rates for each five-year age group, by sex and race, are also required as input data for the cohort component model. The latest available national rates were used because the annual number of deaths in Mississippi is too small to provide reliable information at the state or county level. Because Mississippi tends to lag behind the nation in mortality improvements, survival rates and life expectancy were kept constant over the projection period.

3. Migration - The total number of migrants and the proportion of the total in each age/sex/race category for each projection interval are also required as input data. The number of migrants is positive if a county is experiencing net in-migration and negative if it is experiencing

net out-migration. Migration is the most erratic component in state and substate population projections, since it responds to economic change much more quickly than either births or deaths.

Migration estimates for counties were based on a combination of data from the 2010 Census and the intercensal estimates produced by the U.S. Census Bureau for the period April 1, 2000 to July 1, 2010 -- the latest available data on migration trends. The base period migration estimates were assumed to continue to 2015. Then, because no trend continues indefinitely, migration for all counties was assumed to taper off gradually for the remainder of the projection period. That is, counties with net in-migration continued to experience net in-migration, but at a slower rate, whereas counties having net losses to out-migration were assumed to lose population more gradually relative to the base period.

**These projections are also available online at the following:
